A commuting group where each element is the sum of elements from one finable subset In an abstract algebra, the Abelian group (G, q) is called of course generated, if there is of course many elements x1, ...xs in G in such a way that each x in G can be written in the form of x n1x1 n2x2 ... nsxs with integers n1, ns. In this case, we say that the set x1, ... xs is a generating set of G or that x1, ... xs generate G. Each ultimate Abelian group is generated of course. Of course, the Abellian groups generated can be fully classified. Examples of Integers, (I,) displaystyle (left) (mathbb, right) are of course generated by the abelian group. Integers modulo n 'displaystyle n' , (. . . . . Any direct sum of course of many certainly generated Abel groups is again certainly generated by the Abelian group. Each lattice forms a well-generated free Abelian group. There are no other examples (as opposed to isomorphism). In particular, the group (Yap. . . . x_ x_{1} . . . . . He said . . . . . He said . . . . . then 1/k displaystyle 1/k cannot be generated x 1, ... x n' displaystyle x_{1}, ldots,x_'n. . The group (∗, ·) display (left) (matebb, right) of non-zero rational numbers is also not generated in the final way. Groups of real numbers in addition (R,) displaystyle on the left (mathbb (R) , right) and non-zero real numbers under multiplication (R ∗, ·) displaystyle on the left (mathbbR, cdot on the right) are also not generated. The classification of the Fundamental theorem of course generated by Abelian groups can be indicated in two ways, generalizing two forms of fundamental theorem of the final Abel groups. The theorem, in both forms, in turn generalizes to the structure theorem for the course generated modules over the main ideal domain, which in turn admits further generalizations. The primary decomposition of the primary formulation of decomposition states that each of course generated Abelian group G is isomorphic to a direct sum of primary cyclical groups and infinite cyclical The primary cyclical group is a group whose order is the power of prime. То есть, каждая конечно сгенерированная абелянская группа является изоморфной для группы формы No n ⊕ q 1 ⊕ ⋯ ⊕ q q t , «дисплейный стиль »матхбаб »n'oplus »mathbb »q_{1}'oplus »cdots »oplus »mathbb »q_ t», где n ≥ 0 является рангом, и цифры q1, ..., qt полномочия (не обязательно различные) премьер номера. Specifically, G is finite if and only if No 0. Values n, q1, ... qt (in pre-reshuffled indices) are uniquely defined by G, meaning there is one and only way to present G as such decomposition. Invariant Invariant We can also write any of the of course generated Alelian Group G in the form of a direct amount of form n ⊕ q 1 k_{1} ⊕ ⋯ ⊕ q k u , display mathbb k_ which divides k3 and so on to ku. Again, rank n and invariant factors k1, ... Ku is uniquely defined by G (here with a unique order). Rank and consistency of variant factors determine the group before isomorphism. The equivalence of these statements is equivalent to the result of the Chinese residue theorem, which means that j k ≃ j ⊕ q'displaystyle (mathbb) if and only if j and k are coprime. History History and credit for the basic theorem are complicated by the fact that it was proven when the group theory was not well-established, and thus the early forms, while the necessary modern result and evidence, are often stated for a specific case. In short, the early form of the final case was proven in (Gauss 1801) harv error: no goal: CITEREFGauss1801 (help), the final case was proven in (Kronecker 1870) harv error: no goal: CITEREFKronecker1870 (help), and stated in the group terms theorist in (Frobenius and Stickelberger 1878) harv error: no purpose: CITEREFFrobeniusStickelberger1878 (help). Of course the presented case is solved by the normal smith form, and hence frequently enrolled to (Smith 1861), although the finitely generated case is sometimes instead of enrolled to (Poincar 1900) harv error: no purpose: CITEREFPoincare1900 (help); details follow. The group's theorist, Laszlo Fuchs, says: As for the fundamental theorem of the final Abelian groups, it is not clear how far back in time it is necessary to go to trace its origin. ... It took a long time to formulate and prove the fundamental theoreum in its current form... The fundamental theorem for the ultimate Abelian groups was proven by Leopold Kroneker in (Kronecker 1870) harv error: no purpose: CITEREFKronecker1870 (help), using group theoretic evidence, although not stating it in group theoretical terms; The modern presentation of Kroneker's evidence is given in (Stillwell 2012), Kroneker's theorem 5.2.2 Kronecker, 176-177. This summarized the earlier result of Carl Friedrich Gauss of the Disquisitiones Arithmeticae (1801), who classified the square forms; Kroneker cited Gauss. The theorem was declared and proved in the language of the groups by Ferdinand Georg Frobenius and Ludwig Stikelberger in 1878. Another group theoretic formulation was given by Kroneker's apprentice Eugene Netto in 1882. The fundamental theorem for the of course presented Abelian groups was proved by Henry John Stephen Smith in (Smith 1861), since the integrator matrix corresponds to the final presentations of the Abelian groups (this summarizes the of course modules presented over the main ideal area), and Smith's normal form corresponds to the classification of the course represented by the Abel groups. Teh Theorem for the course generated by the Abelian groups was proven by Henri Poincare in (Poincare 1900) harv error: no goal: CITEREFPoincar 1900 (help), using matrix evidence (which is summarized in the main ideal areas). This was done in the context of calculating the complex's homology, specifically the number ratios and torsion of the Betti measurement complex, where the Betti number corresponds to a number of free parts, and the torsion ratios correspond to the torsion part. It is said in different ways that the fundamental theorem says that of course the Abelian group generated is a direct sum of the free Abelian group of the final rank and the ultimate Abelian group, each of which is unique to isomorphism. The ultimate Abelian group is just a torsion subgroup of G. Rank G defined as the rank free of the Xersion part G; it's just the n number in the above formulas. The consequence of the fundamental theorem is that each of course generated group, free from xersion, is a free Abelian. Of course the generated condition is important here: Display style mathbb is xersion-free, but not free abellian. Each subgroup and factor group of the of course generated abelian group is again fully generated by the abelian. Of course, the Abelian groups, together with a group of homomorphisms, form the Abelian category, which is the subcategory of Serre category of Abel groups. Not the ultimate Abelian groups generate note that not every Abelian group of the final rank is generated of course; Group 1 rank - display - is one counter-example, and a rank-0 group, which gives a direct sum is counted infinitely many copies No. 2 (display style) (mathbb) {2} - another.
